•• ••	•• ••	•• ••

- Ada 1 faktor = pakan ayam
- Ada 3 level pakan (P1, P2, P3)
- Respons = Bobot badan ayam
- Ulangan = 4kali
- Jumlah individu = 96 ekor

RAL: Alokasi materi

Alokasi materi

Materi

Yellow box with 7 yellow dots and 1 blue dot	Green box with 6 green dots	Green box with 6 green dots
Pink box with 6 pink dots	Pink box with 6 pink dots	Green box with 6 green dots
Green box with 6 green dots	Yellow box with 6 yellow dots	Pink box with 6 pink dots
Pink box with 6 pink dots	Yellow box with 6 yellow dots	Yellow box with 6 yellow dots

- Alokasi materi secara acak → Random
 - Dengan random number
 - Atau undian
- Why?

Model statistik

$$Y_{ij} = \mu + P_i + \varepsilon_{ij}$$

Dimana:

Y = Respons

μ = rerata umum

P = pengaruh perlakuan ke-i

ε = eror dari perlakuan ke-i, unit ke-j

$i \in (1,2,3)$ = Level dari faktor

$j \in (1,2, \dots, 96)$ = individu ayam yang digunakan

- Ada 1 faktor = pakan ayam
- Ada 3 level (P1, P2, P3)

Penelitian membandingkan 3 mean +
Cuma 1 faktor:

Analisis data: ANOVA 1 faktor

- Respons = Bobot badan ayam
- Ulangan = 4kali
- Jumlah individu = 96 ekor

2. Rancangan acak Kelompok

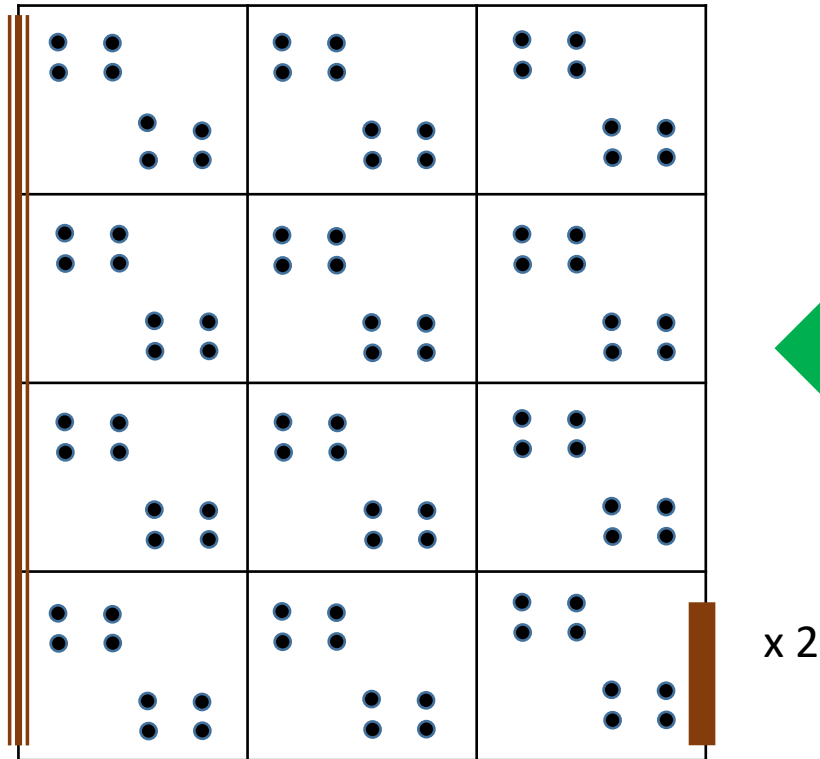

- Ada 1 faktor = pakan ayam
- Ada 3 level pakan (P1, P2, P3)
- Respons = Bobot badan ayam

- Ulangan = 8 kali
- 2 housing yang berbeda
- Jumlah ayam = 192 ekor

RAK: Alokasi materi

Materi

Alokasi materi

Blok 1

Blok 2

Model statistik

$$Y_{ijk} = \mu + B_k + P_i + \varepsilon_{ijk}$$

ANOVA 2 faktor tanpa
interaksi

Dimana:

Y = Respons

μ = rerata umum

B = Blok ke-k

P = pengaruh perlakuan ke-i

ε = eror dari perlakuan ke-i, unit ke-j, blok ke-k

$i \in (1,2,3)$ = Level dari faktor

$j \in (1,2, \dots, 96)$ = individu ayam yang digunakan

$k \in (1,2)$ = jumlah blok

3. Faktorial

- Ada 2 faktor:
 - Pakan ayam
 - Bangsa ayam
- Ada 3 level pakan (P1, P2, P3)
- Ada 2 level bangsa (dot & segitiga)
- Respons = Bobot badan ayam
- Ulangan = 4kali
- Jumlah individu = 192 ekor

*Alokasi materi: Acak

Model statistik

$$Y_{ijk} = \mu + B_k + P_i + B * P_{ik} + \varepsilon_{ijk}$$

Dimana:

Y = Respons

μ = rerata umum

B = Breed ke-k

P = pengaruh perlakuan ke-l

B*P = interaksi breed dengan Pakan

ε = pengaruh eror dari perlakuan ke-i, unit ke-j, blok ke-k

$i \in (1,2,3)$ = Level dari faktor

$j \in (1,2, \dots, 192)$ = individu ayam yang digunakan

$k \in (1,2)$ = jumlah level strain

ANOVA 2 faktor dengan
interaksi

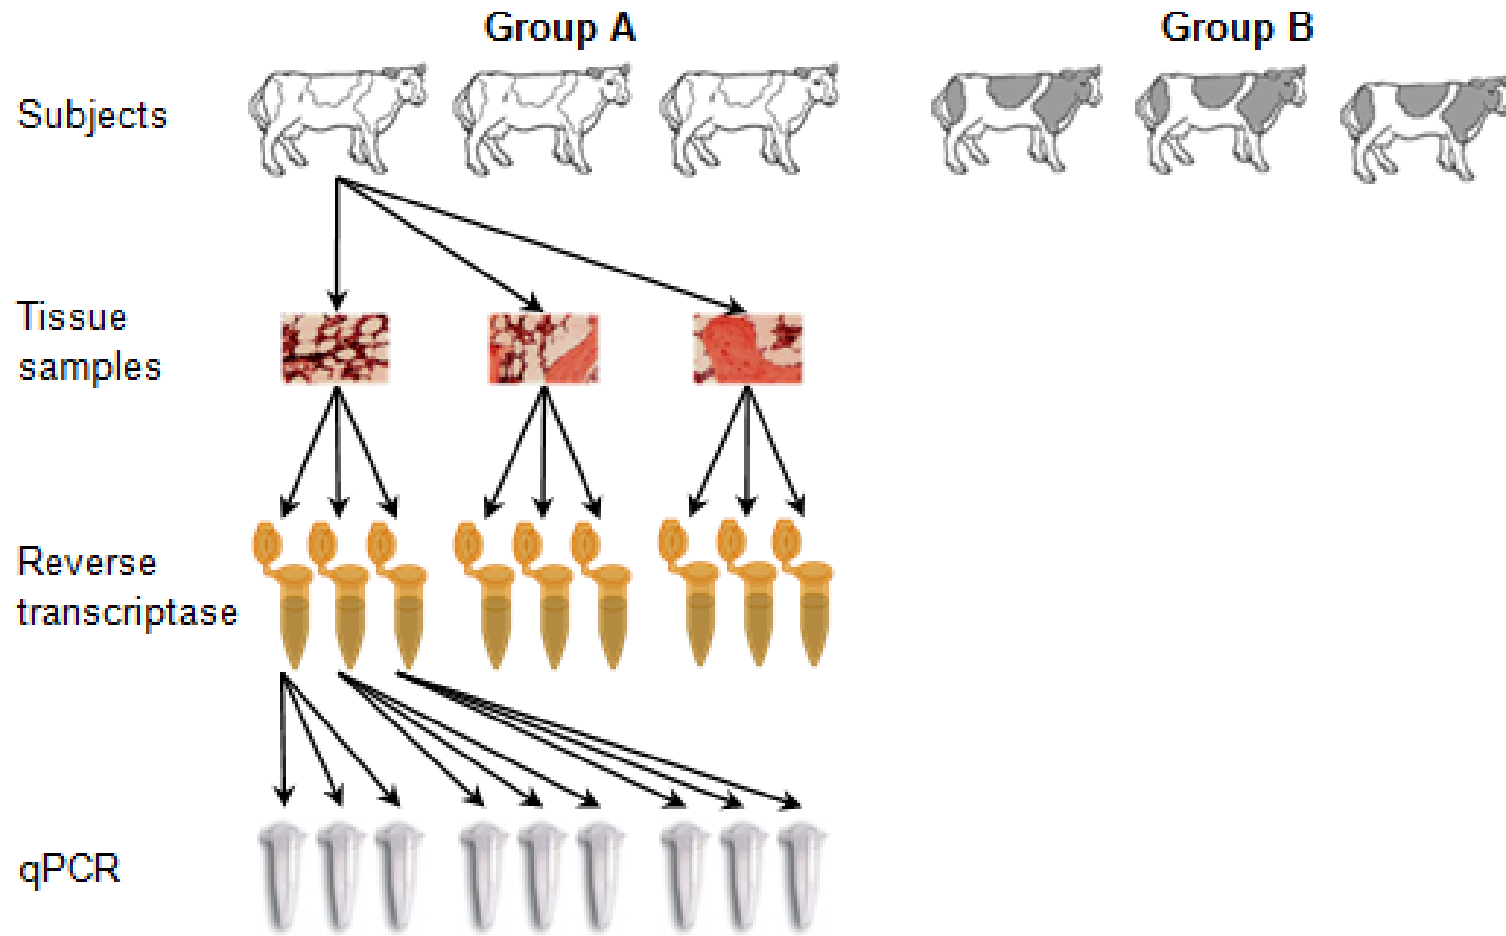

Beberapa jenis rancangan lain

Nested design = pola tersarang

<i>A</i>	<u>1</u>	<u>2</u>	<u>3</u>

	y_{11n}	y_{12n}	y_{13n}	y_{14n}	y_{15n}	y_{16n}	y_{17n}	y_{18n}	y_{19n}

- Lebih dari satu factor
- Terdapat hierarki antara factor pertama dan berikutnya

Contoh

The model for this design is:

$$y_{ijk} = \mu + A_i + B(A)_{ij} + \varepsilon_{ijk} \quad i = 1, \dots, a; \quad j = 1, \dots, b; \quad k = 1, \dots, n$$

where:

y_{ijk} = observation k in level i of factor A and level j of factor B

μ = the overall mean

A_i = the effect of level i of factor A

$B(A)_{ij}$ = the effect of level j of factor B within level i of factor A

ε_{ijk} = random error with mean 0 and variance σ^2

a = the number of levels of A ; b = the number of levels of B ; n = the number of observations per level of B

Split-plot = petak terbagi

One example of a split-plot design has one of the factors applied to main plots in randomized block design. Consider a factor A with four levels (A_1 , A_2 , A_3 and A_4), and a factor B with two levels (B_1 and B_2). The levels of factor A are applied to main plots in three blocks. This is a randomized block plan. Each of the plots is divided into two subplots and the levels of B are randomly assigned to them.

One of the possible plans is:

Block 1	Block 2	Block 3																								
<table border="1"><tr><td>B_2</td><td>B_2</td><td>B_1</td><td>B_2</td></tr><tr><td>B_1</td><td>B_1</td><td>B_2</td><td>B_1</td></tr></table>	B_2	B_2	B_1	B_2	B_1	B_1	B_2	B_1	<table border="1"><tr><td>B_1</td><td>B_2</td><td>B_1</td><td>B_1</td></tr><tr><td>B_2</td><td>B_1</td><td>B_2</td><td>B_2</td></tr></table>	B_1	B_2	B_1	B_1	B_2	B_1	B_2	B_2	<table border="1"><tr><td>B_2</td><td>B_1</td><td>B_2</td><td>B_1</td></tr><tr><td>B_1</td><td>B_2</td><td>B_1</td><td>B_2</td></tr></table>	B_2	B_1	B_2	B_1	B_1	B_2	B_1	B_2
B_2	B_2	B_1	B_2																							
B_1	B_1	B_2	B_1																							
B_1	B_2	B_1	B_1																							
B_2	B_1	B_2	B_2																							
B_2	B_1	B_2	B_1																							
B_1	B_2	B_1	B_2																							
A_4 A_1 A_2 A_3	A_2 A_1 A_4 A_3	A_1 A_2 A_4 A_3																								

The model for this design is:

$$y_{ijk} = \mu + Block_k + A_i + \delta_{ik} + B_j + (AB)_{ij} + \varepsilon_{ijk} \quad i = 1, \dots, a; j = 1, \dots, b; k = 1, \dots, n$$

where:

y_{ijk} = observation k in level i of factor A and level j of factor B

μ = the overall mean

$Block_k$ = the effect of the k^{th} of block

A_i = the effect of level i of factor A

B_j = the effect of level j of factor B

$(AB)_{ij}$ = the effect of the ij^{th} interaction of $A \times B$

δ_{ik} = the main plot error (the interaction $Block_k \times A_i$) with mean and variance σ_δ^2

ε_{ijk} = the split-plot error with mean 0 and variance σ^2

Also, $\mu_{ij} = \mu + A_i + B_j + (AB)_{ij}$ = the mean of ij^{th} $A \times B$ interaction

n = number of blocks

a = number of levels of factor A

b = number of levels of factor B

It is assumed that main plot and split-plot errors are independent.

Bujur sangkar latin

	Column 1	Column 2	Column 3	Column 4
Row 1	T1	T4	T3	T2
Row 2	T3	T2	T1	T4
Row 3	T4	T1	T2	T3
Row 4	T2	T3	T4	T1

What is the model? We let:

$$y_{ijk} = \mu + \rho_i + \beta_j + \tau_k + e_{ijk}$$

$$i = 1, \dots, t$$

$$j = 1, \dots, t$$

$[k = 1, \dots, t]$ where $k = d(i, j)$ and the total number of observations

$N = t^2$ (the number of rows times the number of columns) and t is the number of treatments.
